In graph theory, a cycle in a graph is a non-empty trail in which the only repeated vertices are the first and last vertices. A directed cycle in a directed graph is a non-empty directed trail in which the only repeated vertices are the first and last vertices.. A graph without cycles is called an acyclic graph. A directed graph without directed cycles is called a directed acyclic graph.

But how do we do draw the graph. If we try to approach this problem by using line segments as edges of a graph, we seem to reach nowhere (This sounds confusing initially). Here we need to consider a graph where each line segment is represented as a vertex. Now two vertices of this

In topological graph theory, an embedding (also spelled imbedding) of a graph on a surface is a representation of on in which points of are associated with vertices and simple arcs (homeomorphic images of  $[0,1]$ ) are associated with edges in such a way that: . the endpoints of the arc associated with an edge are the points associated with the end vertices of ,
